I. Objectives

Introduction

A doubly linked list is a type of linked list data structure where each node contains three components:

Data - The actual value stored in the node
Previous pointer - A reference to the previous node in the sequence
Next pointer - A reference to the next node in the sequence.

This laboratory activity aims to implement the principles and techniques in:

- Writing algorithms using Linked list
- Writing a python program that will perform the common operations in a Doubly linked list
- A doubly linked list is particularly useful when you need frequent bidirectional traversal or easy deletion of nodes from both ends of the list.

II. Methods

- Using Google Colab, type the source codes below:

```
class Node:
    """Node class for doubly linked list"""
    def __init__(self, data):
        self.data = data
        self.prev = None
        self.next = None

class DoublyLinkedList:
    """Doubly Linked List implementation"""

    def __init__(self):
        self.head = None
        self.tail = None
        self.size = 0

    def is_empty(self):
        """Check if the list is empty"""
        return self.head is None

    def get_size(self):
        """Get the size of the list"""
```

```
    return self.size

def display_forward(self):
    """Display the list from head to tail"""
    if self.is_empty():
        print("List is empty")
        return

    current = self.head
    print("Forward: ", end="")
    while current:
        print(current.data, end="")
        if current.next:
            print(" ↔ ", end="")
        current = current.next
    print()

def display_backward(self):
    """Display the list from tail to head"""
    if self.is_empty():
        print("List is empty")
        return

    current = self.tail
    print("Backward: ", end="")
    while current:
        print(current.data, end="")
        if current.prev:
            print(" ↔ ", end="")
        current = current.prev
    print()

def insert_at_beginning(self, data):
    """Insert a new node at the beginning"""
    new_node = Node(data)

    if self.is_empty():
        self.head = self.tail = new_node
```

```
        else:
            new_node.next = self.head
            self.head.prev = new_node
            self.head = new_node

        self.size += 1
        print(f"Inserted {data} at beginning")

    def insert_at_end(self, data):
        """Insert a new node at the end"""
        new_node = Node(data)

Answer the following questions:

1. What are the three main components of a Node in the doubly linked list implementation, and what does the __init__ method of the DoublyLinkedList class initialize?
2. The insert_at_beginning method successfully adds a new node to the start of the list. However, if we were to reverse the order of the two lines of code inside the else block, what specific issue would this introduce? Explain the sequence of operations that would lead to this problem:

```
def insert_at_beginning(self, data):
    new_node = Node(data)

    if self.is_empty():
        self.head = self.tail = new_node
    else:
        new_node.next = self.head
        self.head.prev = new_node
        self.head = new_node

    self.size += 1
```

3. How does the reverse method work? Trace through the reversal process step by step for a list containing [A, B, C], showing the pointer changes at each iteration

```
def reverse(self):
    if self.is_empty() or self.head == self.tail:
        return

    current = self.head
    self.tail = self.head

    while current:
        temp = current.prev
        current.prev = current.next
        current.next = temp
```

```
            current = current.prev

        if temp:
            self.head = temp.prev
```

I. Results

ANSWERS:

1)

A. The three main components of a Node in a doubly linked list are: first, **data**, which stores the actual value of the node; second, **prev**, a reference to the previous node in the list; and third, **next**, a reference to the next node in the list.

B. When a new **DoublyLinkedList** object is created, its constructor initializes three main attributes: first, **head**, which is set to **None** to indicate the list has no first node; second, **tail**, also set to **None** to show there's no last node yet; and third, **size**, initialized to **0** to track the number of nodes in the list.

2)

A. If you reverse the two lines inside the **else** block of **insert_at_beginning**, it breaks the proper linking between the new node and the old head. Specifically, you're trying to set the old head's **prev** before the new node knows it's pointing to the head. This causes inconsistent connections and can lead to traversal or logic errors. The correct order ensures both nodes are properly linked before updating the head.

3)

a. The **reverse()** method works by walking through each node in the doubly linked list and swapping its **prev** and **next** pointers. Starting from the head, it reassigns the tail to the current head, then iteratively flips the pointers of each node. After the loop, it updates the head to the last node processed. For a list **[A, B, C]**, the reversal transforms it into **[C, B, A]**, with all links correctly reversed.

II. Conclusion

The **reverse()** method in a doubly linked list efficiently flips the order of nodes by swapping each node's **prev** and **next** pointers during traversal. Starting from the head, it reassigns the tail, walks through the list, and reverses the links in place. After the loop, it updates the head to the new front of the list. For example, reversing **[A, B, C]** results in **[C, B, A]**. This technique showcases how pointer manipulation can achieve structural transformation without extra memory, making it a clean and effective algorithm.
